Please let us know what you thought of your research experience: Did this experience meet your expectations? Were lab personnel helpful and responsive to your needs? What else could have been done to improve your experience or achieve additional results? I was very surprised how much autonomy I had in the beginning of the research. I spent the first week doing training videos for lab and training to learn how to use SketchUp. Then I started modeling simple geometry which then led to simple animations and eventually complex animations. I was always engaged because If I felt exhausted with animating then I could help Dr. Manning in the high bay lab with concrete testing. Each day I was doing something new and when I needed a break, I could take one. All my expectations were surpassed during this program. One thing that could have improved my learning is if there were more students in the same project. I would have enjoyed working with another student and it would have helped me develop more collaboration skills. Overall, research was a great experience, and it was incredibly informative.

## **FINAL WRITTEN REPORT**

Nuclear power plants are expensive to build with long building construction project duration. Decreasing the on-site construction time of nuclear facilities would significantly reduce the overall project costs. Construction of reinforced concrete (RC) buildings by assembling and connecting large, prefabricated modules would allow significant efficiencies in construction. However, state-of-practice connection designs typically used in non-nuclear buildings do not provide the structural strength and stiffness continuity required for nuclear applications. This project, funded by the Nuclear Regulatory Commission, is experimentally and numerically investigating the design, materials, behavior, durability, and construction of lapped connections for safety-related nuclear RC buildings. The novel lapped geometry of the connection provides "face-to-face" (rather than "end-to-end" or "butt") joint interfaces with large surfaces to develop the required continuity of the strength and stiffness of the structure. The lack of straight-line discontinuities across the structure thickness enhances the connection performance. Work conducted as part of the Vincent P. Slatt Fellowship by the Center for Sustainable Energy at Notre Dame developed a visual animation of the proposed construction process for nuclear RC buildings with lapped connections.

The video that was created was useful because it was required for the project proposal. The video is useful to demonstrate how this process would work to the average viewer. The video shows the sequence in which blocks will be placed together like puzzle pieces and connected. The video also illustrates modules with accurate dimensions and the modules also have holes for utility purposes. The video process was also important to highlight constructability. The bracing for example will be slightly different in real life application but the video is still useful because it gives the audience a general understanding that the two connections will be braced using steel plates, threaded steel rods, washers, and nuts.

Here is a copy of my poster that illustrates the sequence in which modules will be placed.

A plate is placed on both sides of connection

Another module is placed

Last module complete building circumference

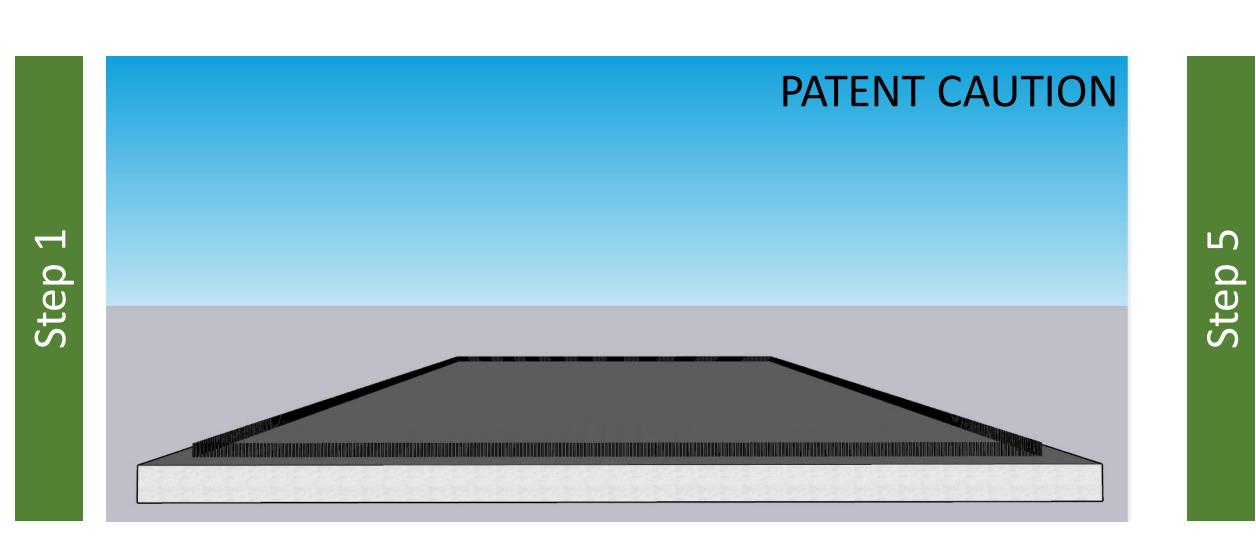

## Animating Construction Process of Modular Lapped Reinforced Concrete Connections to Accelerate Nuclear Building Project Schedules Omar Muñoz, New Mexico State University

## Abstract

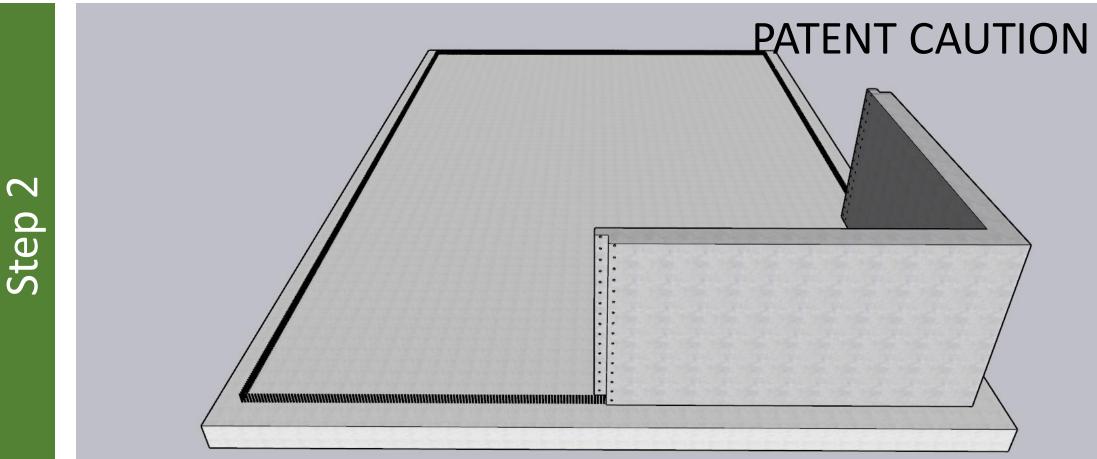

Nuclear power plants are expensive to build with long building construction project durations. Decreasing the onsite construction time of nuclear facilities would significantly reduce the overall project costs. Construction of reinforced concrete (RC) buildings by assembling and connecting large prefabricated modules would allow significant efficiencies in construction. However, state-of-practice connection designs typically used in non-nuclear buildings do not provide the structural strength and stiffness continuity required for nuclear applications. This project, funded by the Nuclear Regulatory Commission, is experimentally and numerically investigating the design, materials, behavior, durability, and construction of lapped connections for safetyrelated nuclear RC buildings. The novel lapped geometry of the connection provides "face-to-face" (rather than "end-to-end" or "butt") joint interfaces with large surfaces to develop the required continuity of the strength and stiffness of the structure. The lack of straight-line discontinuities across the structure thickness enhances the connection performance. Work conducted as part of the Vincent P. Slatt Fellowship by the Center for Sustainable Energy at Notre Dame developed a visual animation of the proposed construction process for nuclear RC buildings with lapped connections.

PATENT CAUTION

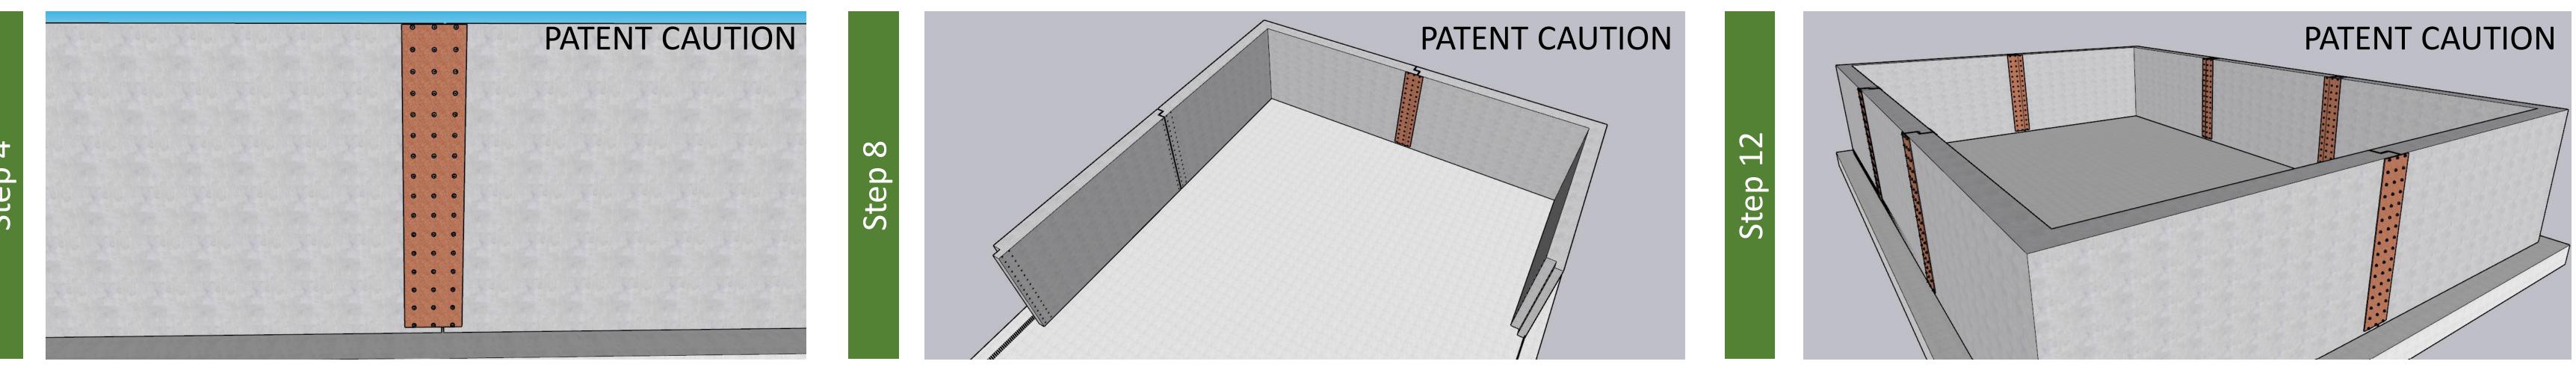

Foundation and rebar are placed in work site

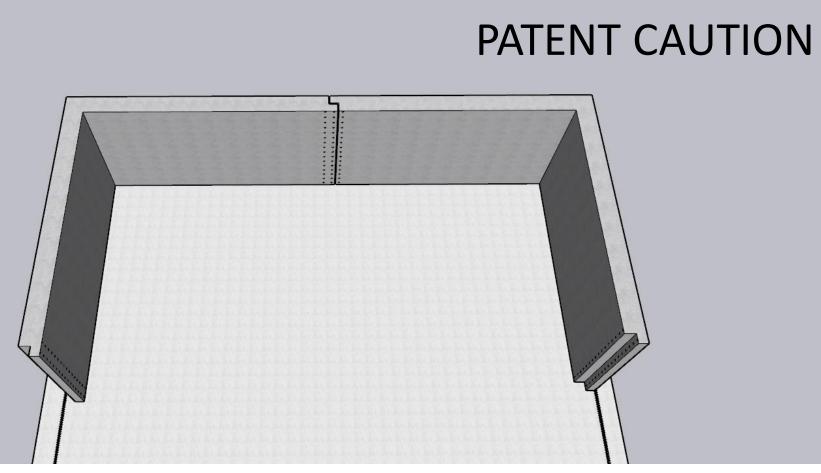

A module is placed on top of foundation

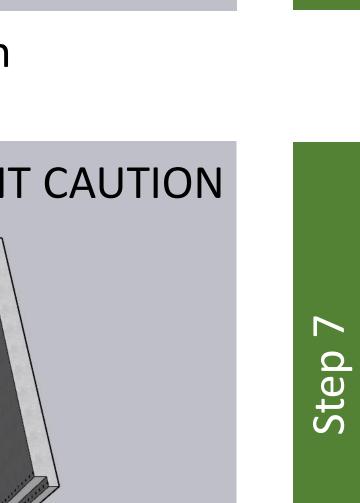

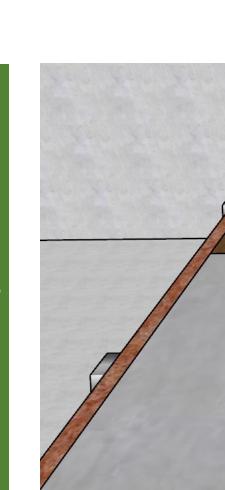

Another module placed next to previous module

A plate is placed on both sides of connection

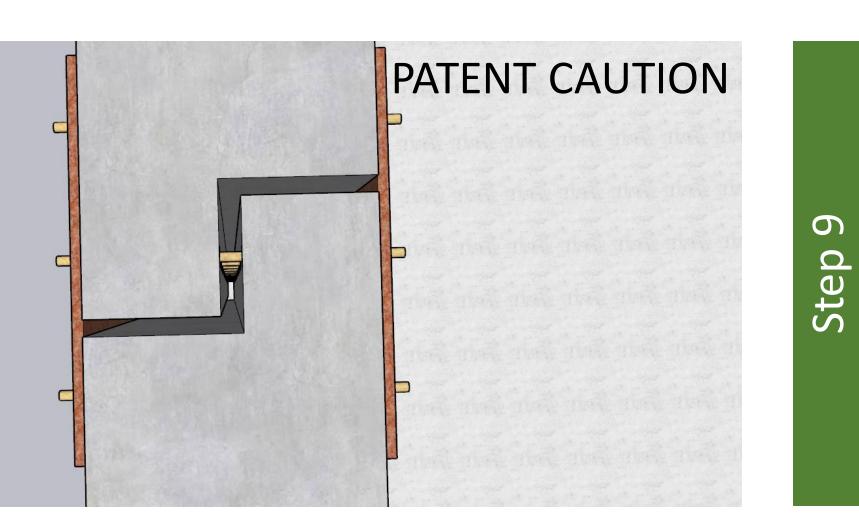

**AT NOTRE DAME** 

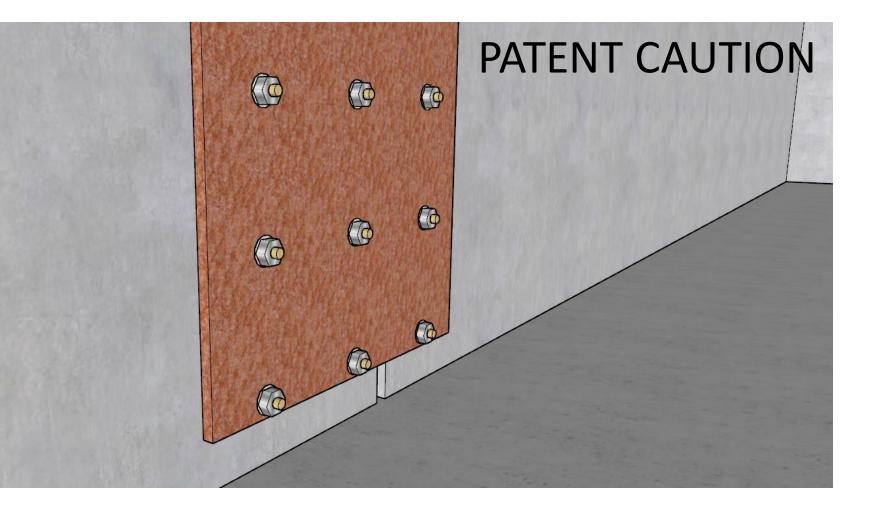

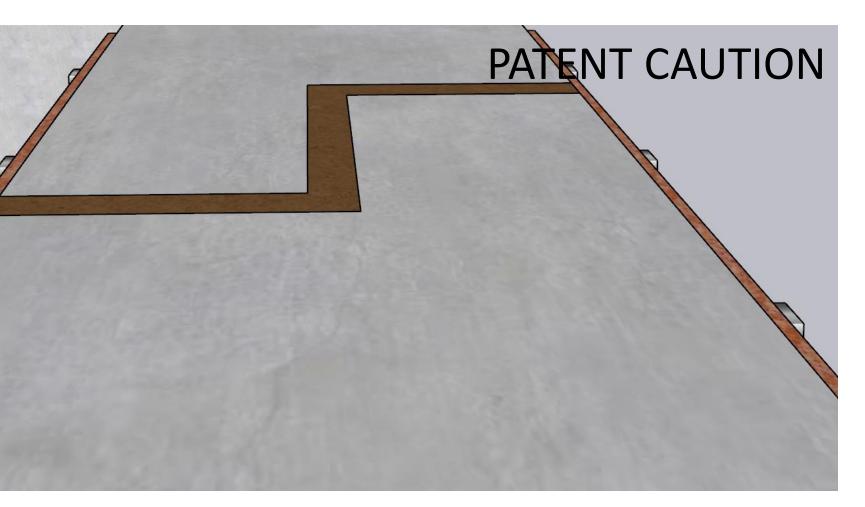

Ω

Washers and nuts are fastened to both sides

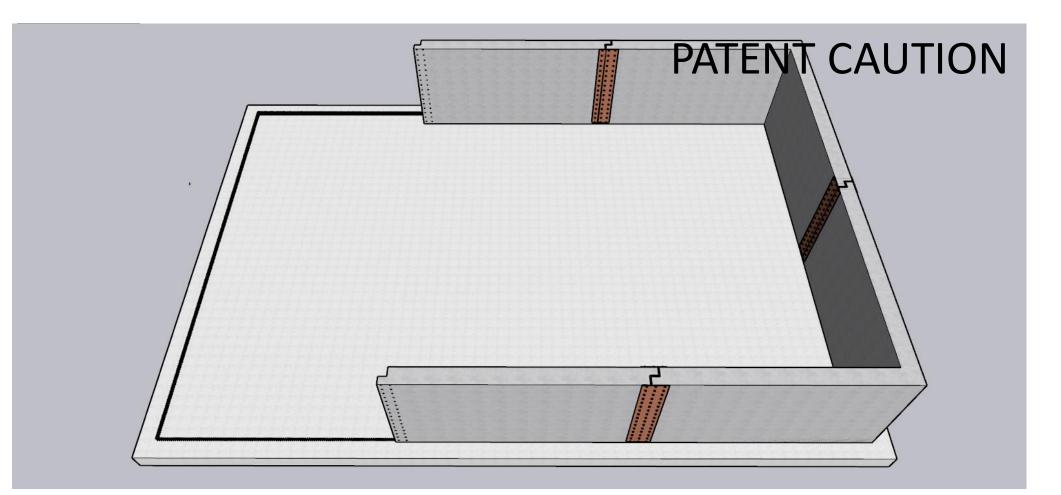

Space is filled with mortar

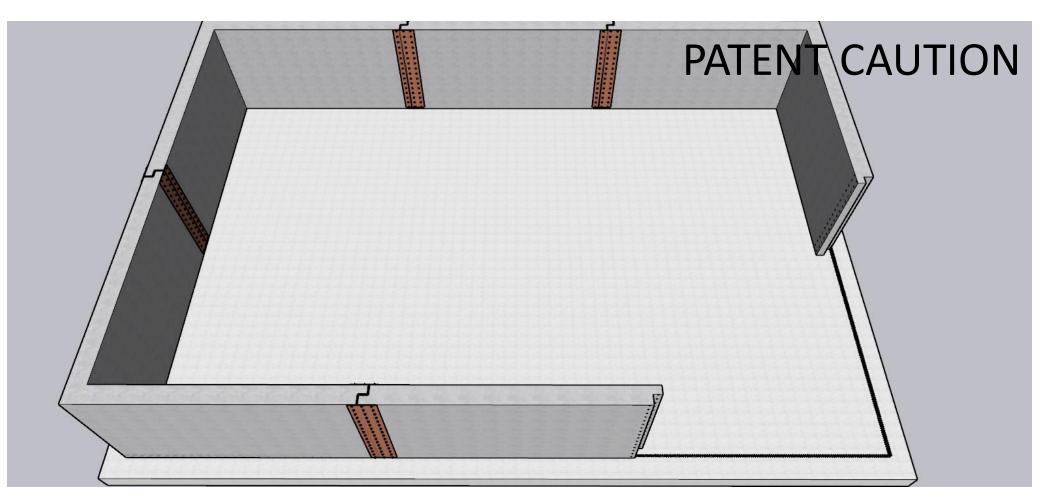

Another module is placed

Step

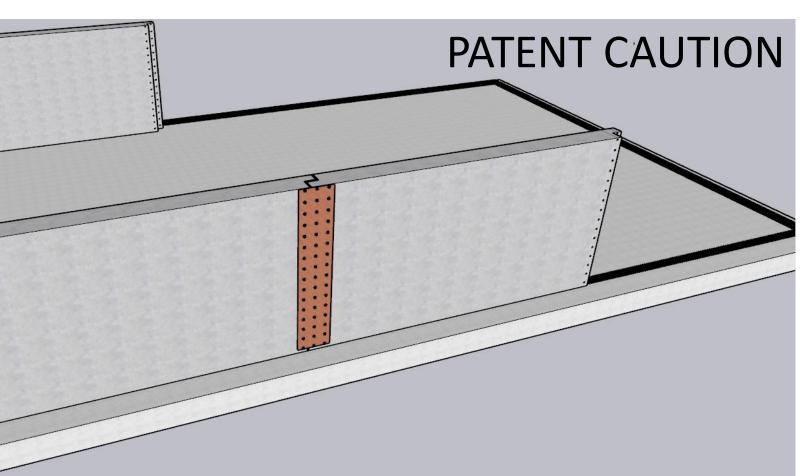

Another module is placed and braced

Third corner is installed

Last module complete building circumference

Same process as step 6
